

Relay protection timing point

Overview

Protection relay setting is the process of choosing the current threshold and time delay at which a relay trips a circuit breaker during a fault. The goal is to isolate only the faulted section — quickly enough to protect equipment, but with enough delay to let downstream relays act. How protective relay testing works: secondary and primary injection, pickup and timing checks, curve verification, and the relay's role in a coordinated scheme. The principle is to grade the operating times of the relays in such a way that. Overcurrent relays are the most common form of protection used to operate only under fault conditions. There are two main types of time relays. Electromechanical relays have moving parts. Ensure that the minimum, un-faulted load is interrupted when the protective.
